

ABSTRACT

A sealable connector comprises a first connector portion, a second connector portion adapted to engage the first connector portion, a compliant material disposed between the first and second connector portions, and a fastening mechanism that secures the first connector portion to the second connector portion, such that a force applied upon the compliant material by the respective first and second connector portions can be adjusted. The fastening mechanism allows a single connector to be utilized for a variety of applications and allows the connector to be adequately sealed regardless of the manufacturing tolerances of the compliant material.
